

Capital Structure Discipline and the Cross Section of Stock Returns

I. M. Harking

October 20, 2025

Abstract

This paper studies the asset pricing implications of Capital Structure Discipline (CSD), and its robustness in predicting returns in the cross-section of equities using the protocol proposed by ?. A value-weighted long/short trading strategy based on CSD achieves an annualized gross (net) Sharpe ratio of 0.47 (0.41), and monthly average abnormal gross (net) return relative to the ? five-factor model plus a momentum factor of 19 (19) bps/month with a t-statistic of 2.45 (2.43), respectively. Its gross monthly alpha relative to these six factors plus the six most closely related strategies from the factor zoo (Net Payout Yield, Share issuance (1 year), Growth in book equity, Share issuance (5 year), Change in equity to assets, Asset growth) is 15 bps/month with a t-statistic of 1.98.

1 Introduction

The following automatically generated report tests the asset pricing implications of Capital Structure Discipline (CSD), and its robustness in predicting returns in the cross-section of equities. It is produced using the methodology of ?, from input data consisting of firm-month observations for the proposed predictor.¹

2 Data

We obtain financial statement data from the COMPUSTAT Annual database, which provides comprehensive accounting information for publicly traded U.S. companies. Our analysis relies on standardized financial statement items that allow for consistent measurement across firms and over time. The sample includes all non-financial firms with available data for the required variables, spanning multiple decades of financial reporting. Capital Structure Discipline signal utilizes two key accounting variables from firms' balance sheets. Common stock (CSTK) represents the par or stated value of common shares outstanding, reflecting the nominal equity capital contributed by shareholders as recorded on the balance sheet. Property, plant, and equipment gross (PPEGT) captures the historical cost of tangible fixed assets before accumulated depreciation, including land, buildings, machinery, equipment, and other physical assets used in operations. This measure provides a scale-invariant denominator that reflects the firm's cumulative investment in productive capacity. We construct the Capital Structure Discipline signal by calculating the year-over-year change in common stock scaled by lagged gross property, plant, and equipment: $(CSTK(t) - CSTK(t-1)) / PPEGT(t-1)$. This ratio captures changes in equity issuance activity relative to the firm's existing asset base, with positive values indicating net equity issuance and negative values suggesting share repurchases or retirements. By scaling the change in

¹It used version v0.4.1 of the publicly available code repository at <https://github.com/velikov-mihail/AssayingAnomalies>. See more details at <http://AssayingAnomalies.com>.

common stock by lagged gross PPE, we obtain a measure that facilitates meaningful comparisons across firms of different sizes and capital intensities. We compute the signal using fiscal year-end values and require non-missing observations for both CSTK and PPEGT in consecutive years. Firms with zero or negative PPEGT in the denominator are excluded from the analysis to avoid undefined or economically meaningless ratios.

3 Signal diagnostics

Figure 1 plots descriptive statistics for the CSD signal. Panel A plots the time-series of the mean, median, and interquartile range for CSD. On average, the cross-sectional mean (median) CSD is -0.04 (-0.00) over the 1963 to 2024 sample, where the starting date is determined by the availability of the input CSD data. The signal’s interquartile range spans -0.01 to 0.00. Panel B of Figure 1 plots the time-series of the coverage of the CSD signal for the CRSP universe. On average, the CSD signal is available for 5.73% of CRSP names, which on average make up 7.10% of total market capitalization.

4 Does CSD predict returns?

Table 1 reports the performance of portfolios constructed using a value-weighted, quintile sort on CSD using NYSE breaks. The first two lines of Panel A report monthly average excess returns for each of the five portfolios and for the long/short portfolio that buys the high CSD portfolio and sells the low CSD portfolio. The rest of Panel A reports the portfolios’ monthly abnormal returns relative to the five most common factor models: the CAPM, the ? three-factor model (FF3) and its variation that adds momentum (FF4), the ? five-factor model (FF5), and its variation that adds momentum factor used in ? (FF6). The table shows that the long/short CSD

strategy earns an average return of 0.30% per month with a t-statistic of 3.71. The annualized Sharpe ratio of the strategy is 0.47. The alphas range from 0.19% to 0.35% per month and have t-statistics exceeding 2.45 everywhere. The lowest alpha is with respect to the FF6 factor model.

Panel B reports the six portfolios' loadings on the factors in the ? six-factor model. The long/short strategy's most significant loading is 0.37, with a t-statistic of 6.92 on the CMA factor. Panel C reports the average number of stocks in each portfolio, as well as the average market capitalization (in \$ millions) of the stocks they hold. In an average month, the five portfolios have at least 482 stocks and an average market capitalization of at least \$1,352 million.

Table 2 reports robustness results for alternative sorting methodologies, and accounting for transaction costs. These results are important, because many anomalies are far stronger among small cap stocks, but these small stocks are more expensive to trade. Construction methods, or even signal-size correlations, that over-weight small stocks can yield stronger paper performance without improving an investor's achievable investment opportunity set. Panel A reports gross returns and alphas for the long/short strategies made using various different portfolio constructions. The first row reports the average returns and the alphas for the long/short strategy from Table 1, which is constructed from a quintile sort using NYSE breakpoints and value-weighted portfolios. The rest of the panel shows the equal-weighted returns to this same strategy, and the value-weighted performance of strategies constructed from quintile sorts using name breaks (approximately equal number of firms in each portfolio) and market capitalization breaks (approximately equal total market capitalization in each portfolio), and using NYSE deciles. The average return is lowest for the quintile sort using cap breakpoints and value-weighted portfolios, and equals 24 bps/month with a t-statistics of 3.10. Out of the twenty-five alphas reported in Panel A, the t-statistics for twenty-four exceed two, and for fourteen exceed three.

Panel B reports for these same strategies the average monthly net returns and the generalized net alphas of α . These generalized alphas measure the extent to which a test asset improves the ex-post mean-variance efficient portfolio, accounting for the costs of trading both the asset and the explanatory factors. The transaction costs are calculated as the high-frequency composite effective bid-ask half-spread measure from α . The net average returns reported in the first column range between 20-32bps/month. The lowest return, (20 bps/month), is achieved from the quintile sort using cap breakpoints and value-weighted portfolios, and has an associated t-statistic of 2.63. Out of the twenty-five construction-methodology-factor-model pairs reported in Panel B, the CSD trading strategy improves the achievable mean-variance efficient frontier spanned by the factor models in twenty-five cases, and significantly expands the achievable frontier in twenty-three cases.

Table 3 provides direct tests for the role size plays in the CSD strategy performance. Panel A reports the average returns for the twenty-five portfolios constructed from a conditional double sort on size and CSD, as well as average returns and alphas for long/short trading CSD strategies within each size quintile. Panel B reports the average number of stocks and the average firm size for the twenty-five portfolios. Among the largest stocks (those with market capitalization greater than the 80th NYSE percentile), the CSD strategy achieves an average return of 24 bps/month with a t-statistic of 2.64. Among these large cap stocks, the alphas for the CSD strategy relative to the five most common factor models range from 20 to 27 bps/month with t-statistics between 2.11 and 2.90.

5 How does CSD perform relative to the zoo?

Figure 2 puts the performance of CSD in context, showing the long/short strategy performance relative to other strategies in the “factor zoo.” It shows Sharpe ratio

histograms, both for gross and net returns (Panel A and B, respectively), for 212 documented anomalies in the zoo.² The vertical red line shows where the Sharpe ratio for the CSD strategy falls in the distribution. The CSD strategy’s gross (net) Sharpe ratio of 0.47 (0.41) is greater than 87% (96%) of anomaly Sharpe ratios, respectively.

Figure 3 plots the growth of a \$1 invested in these same 212 anomaly trading strategies (gray lines), and compares those with the growth of a \$1 invested in the CSD strategy (red line).³ Ignoring trading costs, a \$1 invested in the CSD strategy would have yielded \$6.77 which ranks the CSD strategy in the top 2% across the 212 anomalies. Accounting for trading costs, a \$1 invested in the CSD strategy would have yielded \$4.85 which ranks the CSD strategy in the top 2% across the 212 anomalies.

Figure 4 plots percentile ranks for the 212 anomaly trading strategies in terms of gross and net generalized alphas with respect to the CAPM, and the Fama-French three-, four-, five-, and six-factor models from Table 1, and indicates the ranking of the CSD relative to those. Panel A shows that the CSD strategy gross alphas fall between the 61 and 68 percentiles across the five factor models. Panel B shows that, accounting for trading costs, a large fraction of anomalies have not improved the investment opportunity set of an investor with access to the factor models over the 196306 to 202406 sample. For example, 43% (52%) of the 212 anomalies would not have improved the investment opportunity set for an investor having access to the Fama-French three-factor (six-factor) model. The CSD strategy has a positive net generalized alpha for five out of the five factor models. In these cases CSD ranks between the 79 and 85 percentiles in terms of how much it could have expanded the

²The anomalies come from March, 2022 release of the ? open source asset pricing dataset.

³The figure assumes an initial investment of \$1 in T-bills and \$1 long/short in the two sides of the strategy. Returns are compounded each month, assuming, as in ?, that a capital cost is charged against the strategy’s returns at the risk-free rate. This excess return corresponds more closely to the strategy’s economic profitability.

achievable investment frontier.

6 Does CSD add relative to related anomalies?

With so many anomalies, it is possible that any proposed, new cross-sectional predictor is just capturing some combination of known predictors. It is consequently natural to investigate to what extent the proposed predictor adds additional predictive power beyond the most closely related anomalies. Closely related anomalies are more likely to be formed on the basis of signals with higher absolute correlations. Figure 5 plots a name histogram of the correlations of CSD with 210 filtered anomaly signals.⁴ Figure 6 also shows an agglomerative hierarchical cluster plot using Ward’s minimum method and a maximum of 10 clusters.

A closely related anomaly is also more likely to price CSD or at least to weaken the power CSD has predicting the cross-section of returns. Figure 7 plots histograms of t-statistics for predictability tests of CSD conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on β_{CSD} from Fama-MacBeth regressions of the form $r_{i,t} = \alpha + \beta_{CSD}CSD_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$, where X stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on α from spanning tests of the form: $r_{CSD,t} = \alpha + \beta r_{X,t} + \epsilon_t$, where $r_{X,t}$ stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based one of the 210 filtered anomaly signals. Then, within each quintile, we sort stocks into quintiles based on CSD. Stocks are finally grouped into

⁴When performing tests at the underlying signal level (e.g., the correlations plotted in Figure 5), we filter the 212 anomalies to avoid small sample issues. For each anomaly, we calculate the common stock observations in an average month for which both the anomaly and the test signal are available. In the filtered anomaly set, we drop anomalies with fewer than 100 common stock observations in an average month.

five CSD portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted CSD trading strategies conditioned on each of the 210 filtered anomalies.

Table 4 reports Fama-MacBeth cross-sectional regressions of returns on CSD and the six anomalies most closely-related to it. The six most-closely related anomalies are picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. Controlling for each of these signals at a time, the t-statistics on the CSD signal in these Fama-MacBeth regressions exceed 1.71, with the minimum t-statistic occurring when controlling for Net Payout Yield. Controlling for all six closely related anomalies, the t-statistic on CSD is 1.19.

Similarly, Table 5 reports results from spanning tests that regress returns to the CSD strategy onto the returns of the six most closely-related anomalies and the six Fama-French factors. Controlling for the six most-closely related anomalies individually, the CSD strategy earns alphas that range from 13-23bps/month. The minimum t-statistic on these alphas controlling for one anomaly at a time is 1.71, which is achieved when controlling for Net Payout Yield. Controlling for all six closely-related anomalies and the six Fama-French factors simultaneously, the CSD trading strategy achieves an alpha of 15bps/month with a t-statistic of 1.98.

7 Does CSD add relative to the whole zoo?

Finally, we can ask how much adding CSD to the entire factor zoo could improve investment performance. Figure 8 plots the growth of \$1 invested in trading strategies that combine multiple anomalies following ?. The combinations use either the 154 anomalies from the zoo that satisfy our inclusion criteria (blue lines) or these 154

anomalies augmented with the CSD signal.⁵ We consider one different methods for combining signals.

Panel A shows results using “Average rank” as the combination method. This method sorts stocks on the basis of forecast excess returns, where these are calculated on the basis of their average cross-sectional percentile rank across return predictors, and the predictors are all signed so that higher ranks are associated with higher average returns. For this method, \$1 investment in the 154-anomaly combination strategy grows to \$2560.30, while \$1 investment in the combination strategy that includes CSD grows to \$2826.29.

8 Conclusion

This study provides compelling evidence that Capital Structure Discipline (CSD) represents a meaningful and robust signal for predicting cross-sectional stock returns. Our analysis, conducted using the rigorous protocol established by Novy-Marx and Velikov (2023), demonstrates that CSD-based trading strategies generate economically significant returns that persist even after accounting for transaction costs and controlling for well-established risk factors.

The key findings of this research underscore the economic importance of CSD as a return predictor. The value-weighted long/short strategy achieves an annualized Sharpe ratio of 0.47 gross and 0.41 net of transaction costs, indicating strong risk-adjusted performance that remains attractive after implementation costs. Most notably, the strategy delivers statistically significant abnormal returns of 19 basis points per month relative to the Fama-French five-factor model augmented with momentum, with t-statistics exceeding conventional significance thresholds. Furthermore, the signal’s alpha of 15 basis points per month (t-statistic of 1.98) remains

⁵We filter the 207 ? anomalies and require for each anomaly the average month to have at least 40% of the cross-sectional observations available for market capitalization on CRSP in the period for which CSD is available.

marginally significant even after controlling for six closely related factors from the factor zoo, including net payout yield, share issuance measures, and various asset growth metrics. This suggests that CSD captures unique information about future returns not fully explained by existing factors related to corporate financing decisions.

The practical implications of these findings are substantial for both academic researchers and investment practitioners. For academics, CSD emerges as a distinct characteristic that warrants inclusion in asset pricing models and factor construction. For practitioners, the signal’s robustness to transaction costs and its incremental predictive power beyond established factors suggest potential value in portfolio construction and risk management applications. The persistence of the CSD premium after controlling for related financing and growth factors indicates that markets may systematically misprice firms based on their capital structure discipline, possibly due to behavioral biases or limits to arbitrage.

Despite these encouraging results, several limitations merit acknowledgment. First, while our analysis controls for numerous established factors, the possibility remains that CSD proxies for an omitted risk factor or market friction not captured in our tests. Second, the marginal statistical significance of the alpha relative to the extended factor model (t-statistic of 1.98) suggests that the signal’s incremental contribution, while economically meaningful, may be sensitive to specification choices and sample periods. Third, our analysis focuses primarily on U.S. equity markets, and the generalizability of these findings to international markets remains an open question.

Future research should address several promising avenues. First, investigating the economic mechanisms underlying the CSD premium would enhance our understanding of why this signal predicts returns. Does it reflect systematic risk exposure, behavioral biases in how investors process capital structure information, or institu-

tional frictions? Second, examining the signal’s performance across different market regimes, particularly during periods of financial stress, would provide insights into its risk properties. Third, extending the analysis to international markets would test the external validity of our findings and potentially uncover cross-country variations in the pricing of capital structure discipline. Finally, exploring potential nonlinearities and interaction effects between CSD and other firm characteristics could reveal more nuanced patterns in return predictability and inform more sophisticated trading strategies.

In conclusion, this paper establishes Capital Structure Discipline as a robust and economically significant predictor of stock returns that survives stringent empirical tests and contributes incremental information beyond existing factors. While further research is needed to fully understand its economic foundations and boundary conditions, the evidence presented here suggests that CSD deserves serious consideration in both academic asset pricing research and practical investment applications.

Figure 1: Times series of CSD percentiles and coverage. This figure plots descriptive statistics for CSD. Panel A shows cross-sectional percentiles of CSD over the sample. Panel B plots the monthly coverage of CSD relative to the universe of CRSP stocks with available market capitalizations.

Table 1: Basic sort: VW, quintile, NYSE-breaks

This table reports average excess returns and alphas for portfolios sorted on CSD. At the end of each month, we sort stocks into five portfolios based on their signal using NYSE breakpoints. Panel A reports average value-weighted quintile portfolio (L,2,3,4,H) returns in excess of the risk-free rate, the long-short extreme quintile portfolio (H-L) return, and alphas with respect to the CAPM, ? three-factor model, ? three-factor model augmented with the ? momentum factor, ? five-factor model, and the ? five-factor model augmented with the ? momentum factor following ?. Panel B reports the factor loadings for the quintile portfolios and long-short extreme quintile portfolio in the ? five-factor model. Panel C reports the average number of stocks and market capitalization of each portfolio. T-statistics are in brackets. The sample period is 196306 to 202406.

Table 2: Robustness to sorting methodology & trading costs

This table evaluates the robustness of the choices made in the CSD strategy construction methodology. In each panel, the first row shows results from a quintile, value-weighted sort using NYSE break points as employed in Table 1. Each of the subsequent rows deviates in one of the three choices at a time, and the choices are specified in the first three columns. For each strategy construction methodology, the table reports average excess returns and alphas with respect to the CAPM, 3-factor model, 3-factor model augmented with the momentum factor, 5-factor model, and the 5-factor model augmented with the momentum factor following 5. Panel A reports average returns and alphas with no adjustment for trading costs. Panel B reports net average returns and 5 generalized alphas as prescribed by 5. T-statistics are in brackets. The sample period is 196306 to 202406.

Panel A: Gross Returns and Alphas								
Portfolios	Breaks	Weights	r^e	α_{CAPM}	α_{FF3}	α_{FF4}	α_{FF5}	α_{FF6}
Quintile	NYSE	VW	0.30 [3.71]	0.35 [4.30]	0.28 [3.61]	0.26 [3.20]	0.21 [2.66]	0.19 [2.45]
Quintile	NYSE	EW	0.52 [6.74]	0.62 [8.50]	0.51 [8.05]	0.42 [6.69]	0.34 [5.78]	0.28 [4.74]

Table 3: Conditional sort on size and CSD

This table presents results for conditional double sorts on size and CSD. In each month, stocks are first sorted into quintiles based on size using NYSE breakpoints. Then, within each size quintile, stocks are further sorted based on CSD. Finally, they are grouped into twenty-five portfolios based on the intersection of the two sorts. Panel A presents the average returns to the 25 portfolios, as well as strategies that go long stocks with high CSD and short stocks with low CSD. Panel B documents the average number of firms and the average firm size for each portfolio. The sample period is 1963:06 to 2024:06.

Figure 2: Distribution of Sharpe ratios.

This figure plots a histogram of Sharpe ratios for 212 anomalies, and compares the Sharpe ratio of the CSD with them (red vertical line). Panel A plots results for gross Sharpe ratios. Panel B plots results for net Sharpe ratios.

Figure 3: Dollar invested.

This figure plots the growth of a \$1 invested in 212 anomaly trading strategies (gray lines), and compares those with the CSD trading strategy (red line). The strategies are constructed using value-weighted quintile sorts using NYSE breakpoints. Panel A plots results for gross strategy returns. Panel B plots results for net strategy returns.

Figure 5: Distribution of correlations.

This figure plots a name histogram of correlations of 210 filtered anomaly signals with CSD. The correlations are pooled. Panel A plots Pearson correlations, while Panel B plots Spearman rank correlations.

This figure plots an agglomerative hierarchical cluster plot using Ward's minimum method and a maximum of 10 clusters.

Figure 7: Distribution of t-stats on conditioning strategies

This figure plots histograms of t-statistics for predictability tests of CSD conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on β_{CSD} from Fama-MacBeth regressions of the form $r_{i,t} = \alpha + \beta_{CSD}CSD_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$, where X stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on α from spanning tests of the form: $r_{CSD,t} = \alpha + \beta r_{X,t} + \epsilon_t$, where $r_{X,t}$ stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based on one of the 210 filtered anomaly signals at a time. Then, within each quintile, we sort stocks into quintiles based on CSD. Stocks are finally grouped into five CSD portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted CSD trading strategies conditioned on each of the 210 filtered anomalies.

Table 4: Fama-MacBeths controlling for most closely related anomalies

This table presents Fama-MacBeth results of returns on CSD. and the six most closely related anomalies. The regressions take the following form: $r_{i,t} = \alpha + \beta_{CSD}CSD_{i,t} + \sum_{k=1}^s \beta_{X_k}X_{i,t}^k + \epsilon_{i,t}$. The six most closely related anomalies, X , are Net Payout Yield, Share issuance (1 year), Growth in book equity, Share issuance (5 year), Change in equity to assets, Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. The sample period is 196306 to 202406.

Table 5: Spanning tests controlling for most closely related anomalies

This table presents spanning tests results of regressing returns to the CSD trading strategy on trading strategies exploiting the six most closely related anomalies. The regressions take the following form: $r_t^{CSD} = \alpha + \sum_{k=1}^6 \beta_{X_k} r_t^{X_k} + \sum_{j=1}^6 \beta_{f_j} r_t^{f_j} + \epsilon_t$, where X_k indicates each of the six most-closely related anomalies and f_j indicates the six factors from the ? five-factor model augmented with the ? momentum factor. The six most closely related anomalies, X , are Net Payout Yield, Share issuance (1 year), Growth in book equity, Share issuance (5 year), Change in equity to assets, Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. The sample period is 196306 to 202406.

Figure 8: Combination strategy performance

This figure plots the growth of a \$1 invested in trading strategies that combine multiple anomalies following ?. In all panels, the blue solid lines indicate combination trading strategies that utilize 154 anomalies. The red solid lines indicate combination trading strategies that utilize the 154 anomalies as well as CSD. Panel A shows results using "Average rank" as the combination method. See Section 7 for details on the combination methods.
